

Case Study: Token-level rewards for an incorrect ($r = 0$) student generation excerpt

We will use symmetry and known geometry properties. Key geometric insight — distance from a point on the angle's incircle to the two sides. There is a known property of a point on the circle tangent to the two sides of an angle: The sum of the perpendicular distances from any point on the circle (tangent to both sides of an angle) to the two sides of the angle is constant and equal to the distance between the points of tangency, or more precisely, equal to twice the inradius (in terms of a particular coordinate setup),
